A 23-year-old man presented to the Emergency Department (ED) with severe right testicular pain, which progressively increased throughout the day and worsened three hours prior to presentation. On physical examination, the right hemiscrotum was tender, and the testicle was palpated lying high and transversely. A tentative diagnosis of testicular torsion was made based on the classic clinical findings.

Bedside ultrasound examination was performed in the ED with the ZONARE Z.One PRO imaging platform. The examination revealed an enlarged right testicle with heterogeneous sonographic texture, thickened scrotal skin (Figure 1), and a markedly dilated and edematous epididymis and spermatic cord (Figure 2). Power Doppler imaging failed to demonstrate blood flow within the spermatic cord or testicular parenchyma (Figure 3), a pathognomonic finding when using a highly sensitive Doppler ultrasound imaging system.

The patient was transported to the surgical suite within thirty-five minutes after admission to the ED where the diagnosis of testicular torsion was confirmed. The right testicle had twisted four times on the spermatic cord pedicle. After detorsion, blood flow returned to the testicle and it was determined to be viable. Because of a quick and accurate diagnosis, the testicle was saved and the patient enjoyed an uneventful recovery.

Testicular torsion constitutes a true urological emergency that requires quick and accurate differentiation from other sources of scrotal pain. It is a common condition, particularly in adolescent and young adult males, accounting for over a quarter of cases of acute scrotum. Delayed diagnosis and management can result in loss of the testicle. While the clinical presentation and physical finding in these cases are typical, the use of bedside ultrasound can significantly improve diagnostic accuracy and outcomes.
patients is highly suggestive of a torsed testicle, high resolution B-mode ultrasound imaging coupled with exquisitely sensitive color and power Doppler modes, both hallmarks of the ZONARE line of products, has been validated as a routine preoperative diagnostic tool in assessment of patients presenting to the ED with acute scrotum.

Figure 3: Power Doppler imaging fails to demonstrates perfusion.
